STA 235 - Causal Inference: Regression Discontinuity Design (Cont.)

Spring 2021

McCombs School of Business, UT Austin

Reminders

In-class midterm March 29th

- What will the midterm look like?
 - Shorter version of a homework: Examples/cases with data (conceptual + R code)
- Where should I study from?
 - R code posted for class (includes conceptual questions), R code example questions for midterm, examples/questions seen in class, JITTs, etc.
 - Other resources posted on the bookmark section (websites have a lot of data exercises)
 - Don't memorize anything.

Today

- Quick recap and finish with regression discontinuity design:
 - How do we estimate an effect in an RD?
- Instrumental variables
 - Noncompliance in RCTs.
 - Fuzzy regression discontinuity designs.

Let's recap

Behind the scenes of RDs

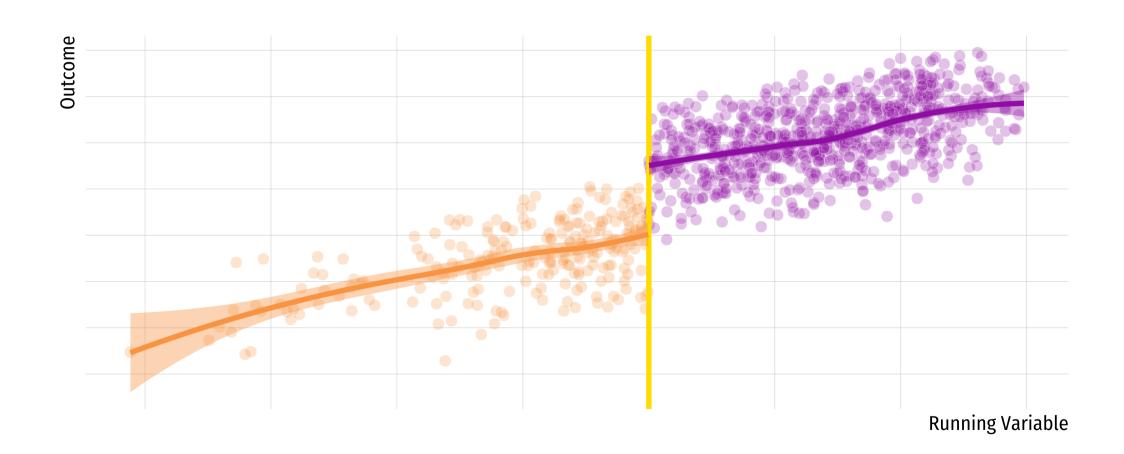

- Basically, regression discontinuities work under an **asymptotic assumption**:
- Let Y_i be the outcome of interest, Z_i the treatment assignment, R_i the running variable, and c the cutoff score:

$$Z_i = \left\{egin{array}{ll} 0 & R_i \leq c \ 1 & R_i > c \end{array}
ight.$$

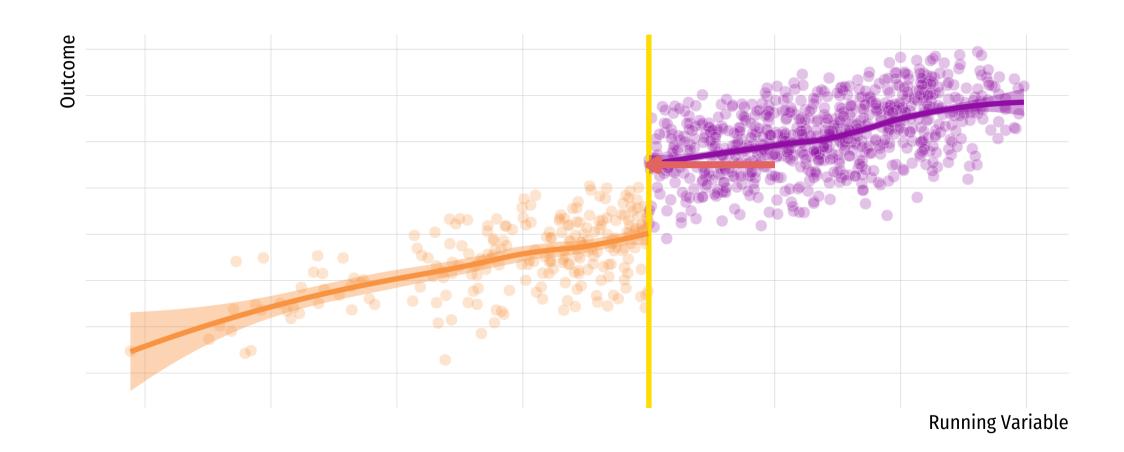

ullet Then, we can define the treatment effect δ as:

$$\delta = \lim_{\epsilon o 0^+} E[Y_i | R_i = c + \epsilon] - \lim_{\epsilon o 0^-} E[Y_i | R_i = c + \epsilon]$$

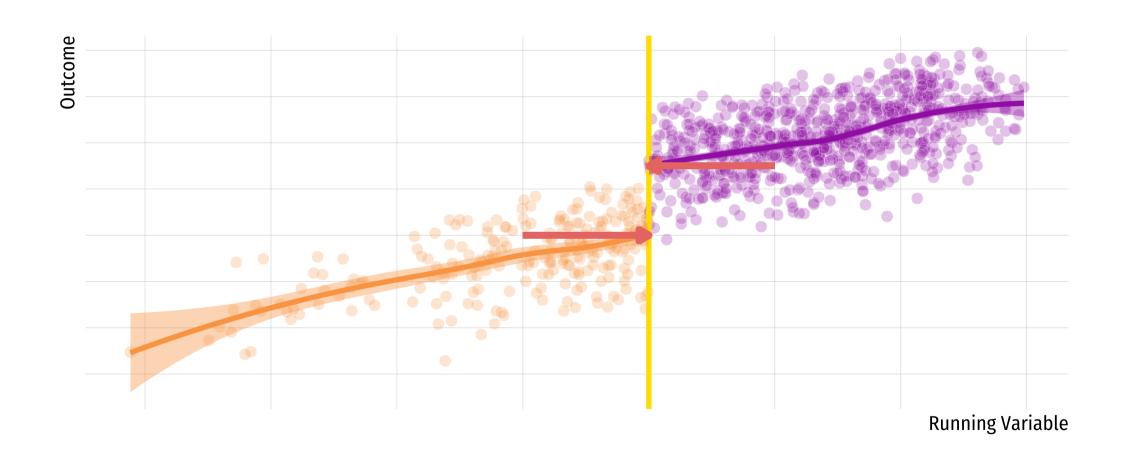

What does the limit expression mean?

What does the limit expression mean?

What does the limit expression mean?

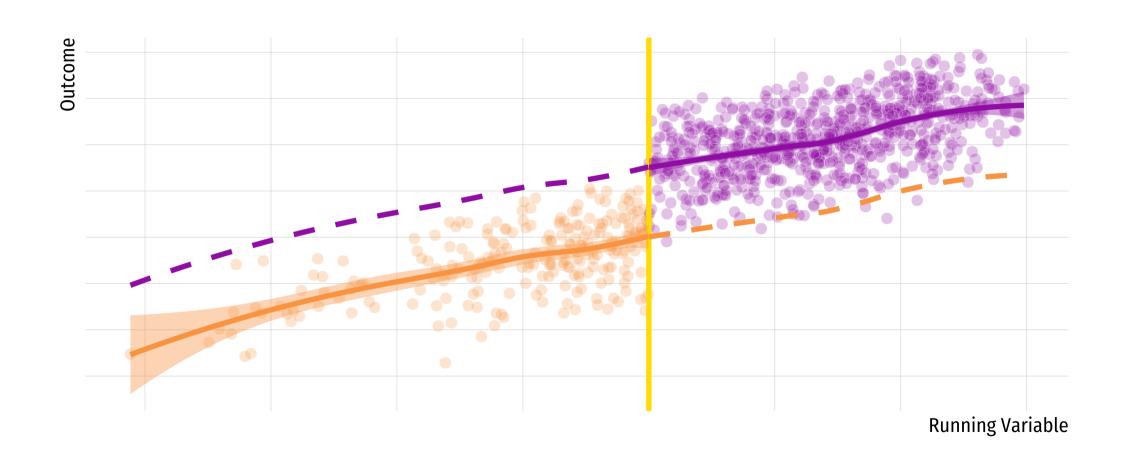

Conditions required for identification

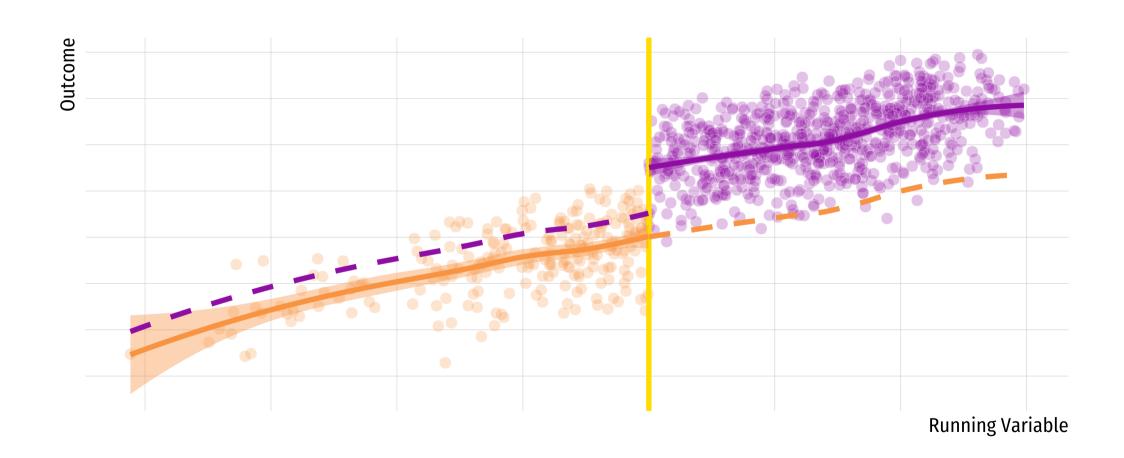

- Threshold rule exists and cutoff point is known
- The running variable R_i is **continuous** near c.
- Key assumption:

Continuity of E[Y(1)|R] and E[Y(0)|R] at R=c

Potential outcomes need to be smooth across the threshold

Potential outcomes need to be smooth across the threshold

How can I check if this assumption holds?

You can't! (it's an assumption)

Robustness checks:

- Check density across the cutoff
- Check RD for covariates

Estimation in practice

How do we actually estimate an RD?

• The simplest way to do this is to fit a regression:

$$Y_i = eta_0 + eta_1(R_i - c) + eta_2 \mathrm{I}[R_i > c] + eta_3(R_i - c)\mathrm{I}[R_i > c]$$

How do we actually estimate an RD?

The simplest way to do this is to fit a regression:

$$Y_i = eta_0 + eta_1$$
 $(R_i - c)$ $+ eta_2 \mathrm{I}[R_i > c] + eta_3$ $(R_i - c)$ $\mathrm{I}[R_i > c]$

How do we actually estimate an RD?

The simplest way to do this is to fit a regression:

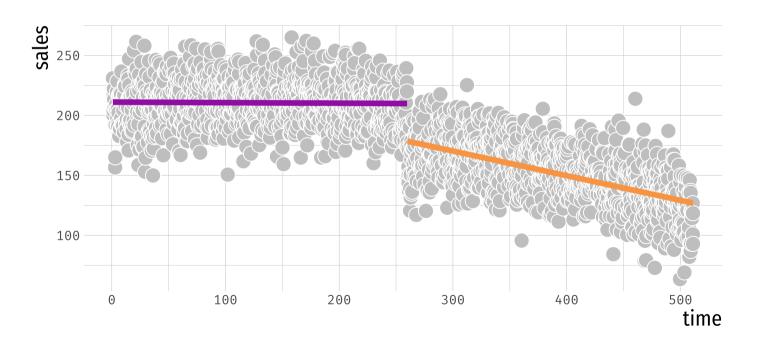

$$Y_i = eta_0 + eta_1(R_i-c) + eta_2 \overline{\mathbf{I}[R_i>c]} + eta_3(R_i-c) \overline{\mathbf{I}[R_i>c]}$$

You want to add flexibility for each side of the cutoff.

Can you identify these parameters in a plot?

Let's see some examples: Sales using a linear model

```
sales <- sales %>% mutate(dist = c-time)
lm(sales ~ dist + treat + dist*treat, data = sales)
```

Let's see some examples: Sales using a linear model

```
summary(lm(sales ~ dist + treat + dist*treat, data = sales))
##
## Call:
## lm(formula = sales ~ dist + treat + dist * treat, data = sales)
##
## Residuals:
      Min
              10 Median 30
                                    Max
## -65.738 -13.940 0.051 13.538 76.515
##
## Coefficients:
                Estimate Std. Error t value Pr(>|t|)
##
## (Intercept) 178.640954   1.300314   137.38   <2e-16 ***
               0.205355    0.008882    23.12    <2e-16 ***
## dist
## treat 31.333952 1.842338 17.01 <2e-16 ***
## dist:treat -0.200845 0.012438 -16.15 <2e-16 ***
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 20.52 on 1996 degrees of freedom
## Multiple R-squared: 0.6939, Adjusted R-squared: 0.6934
## F-statistic: 1508 on 3 and 1996 DF, p-value: < 2.2e-16
```

We can be more flexible

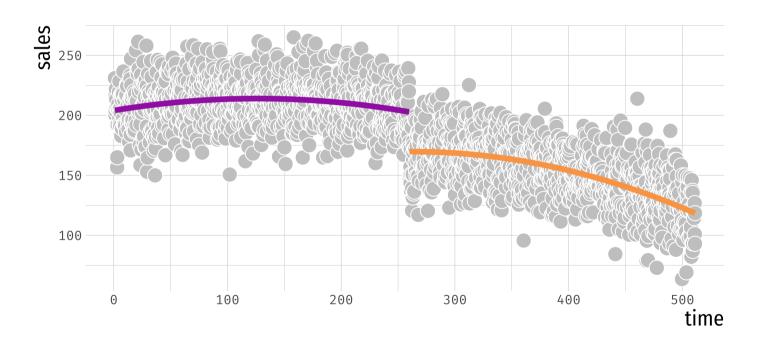

• The previous example just included linear terms, but you can also be more flexible:

$$Y_i = \beta_0 + \beta_1 f(R_i - c) + \beta_2 I[R_i > c] + \beta_3 f(R_i - c) I[R_i > c]$$

ullet Where f is any function you want.

What happens if we fit a quadratic model?

```
lm(sales ~ dist + I(dist^2) + treat + dist*treat + treat*I(dist^2), data = sales)
```

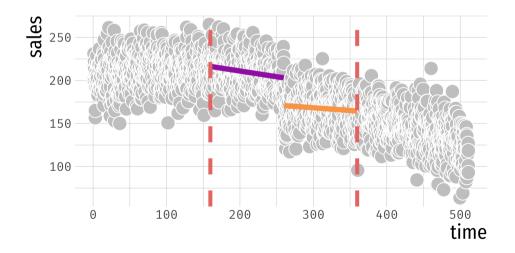

What happens if we fit a quadratic model?

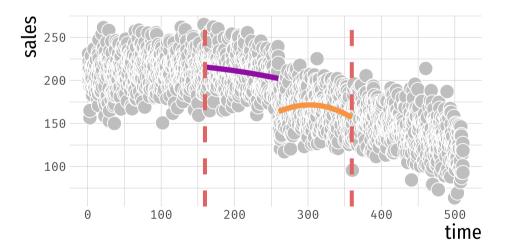

```
summary(lm(sales ~ dist + I(dist^2) + treat + dist*treat + treat*I(dist^2), data = sales))
##
## Call:
## lm(formula = sales ~ dist + I(dist^2) + treat + dist * treat +
##
      treat * I(dist^2), data = sales)
##
## Residuals:
##

```

Potential problems

- There are **many potential problems** with the previous examples:
 - Which polynomial function should we choose? Linear, quadratic, other?
 - What bandwidth should we choose? Whole sample? [-100,100]?

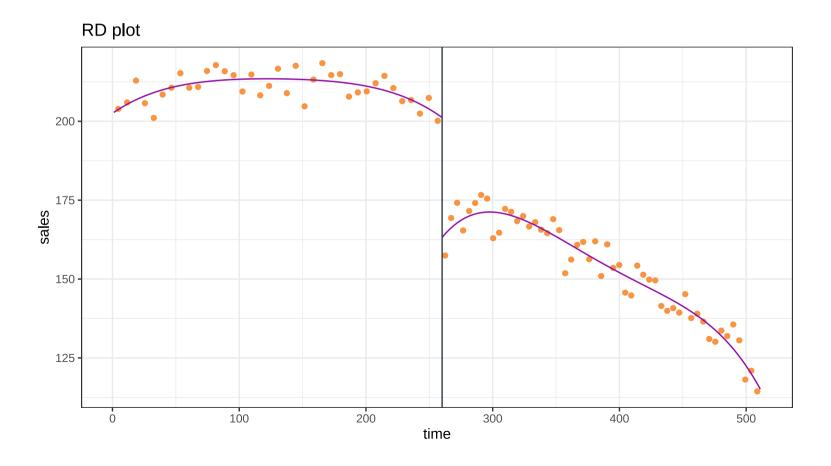

- There are some ways to address these concerns.

Package rdrobust

- Robust Regression Discontinuity introduced by Cattaneo, Calonico, Farrell & Titiunik (2014).
- Use of **local polynomial** for fit.
- Data-driven optimal bandwidth (bias vs variance).
- rdrobust: Estimation of LATE and opt. bandwidth
- rdplot: Plotting RD with nonparametric local polynomial.

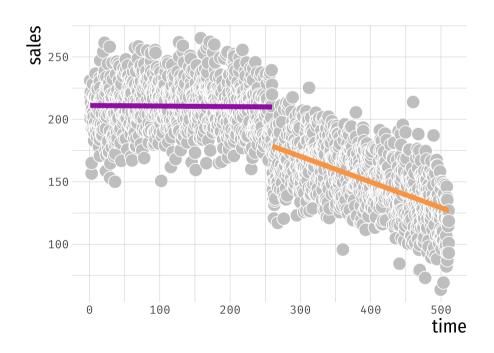

Let's compare with previous parametric results

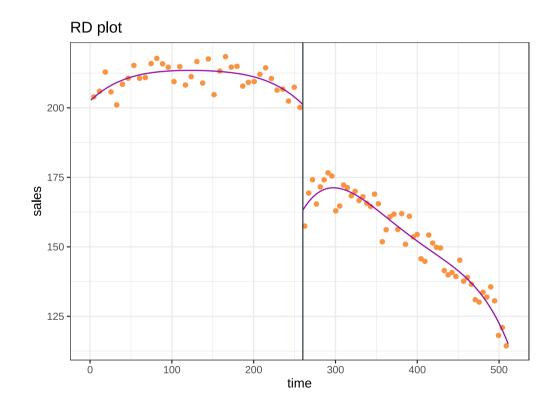

```
rdplot(y = sales$sales, x = sales$time, c = c,
    title = "RD plot", x.label = "time", y.label = "sales")
```

Let's compare with previous parametric results

```
rdplot(y = sales$sales, x = sales$time, c = c,
    title = "RD plot", x.label = "time", y.label = "sales")
```

Let's compare with previous parametric results

```
summary(rdrobust(y = sales$sales, x = sales$time, c = c))

##
           Robust
```

How do we weight observations?

- rdrobust uses rdbwselect() function (by default) to estimate a data-driven bandwidth (i.e. what observations we are going to use for estimation).
 - If we use a bandwidth, does this mean that the RD is estimating an effect for that population within the bandwidth?
- **Kernels** are also important in this context:
 - How do I weight observations within the bandwidth (e.g. uniform, triangle)

Observing kernels

Now it's your turn

Example: Tutoring program according to entrance exam

Outcome: Exit exam

In-class exercise

Instructions:

- You will be sorted into groups.
- Download the R Script for the course website or link provided.
- Discuss with your group. You will need to talk to each other.
- Write down your answers in your script, and upload it to Canvas if you want to submit it.

Takeaway points

- RD designs are **great** for causal inference!
 - Strong internal validity
 - Number of robustness checks
- Limited external validity.
- Make sure to check your data:
 - Discontinuity in treatment assignment
 - Density across the cutoff
 - Smoothness of covariates
